### Kernel Methods

He He

Slides based on Lecture 4d from David Rosenberg's course material.

CDS, NYU

February 21, 2023

#### Today's lecture:

- Wrap-up SVM
- Motivation of kernel methods: Our data is typically not linearly separable, but we like to work with linear models.
- Adding features (going to high-dimensional space) allow us to use linear models for complex data.
- Kernels allow us to think about similarities rather than feature engineering.

Feature Maps

# The Input Space $\mathfrak X$

- ullet Our general learning theory setup: no assumptions about  ${\mathcal X}$
- But  $\mathfrak{X} = \mathbb{R}^d$  for the specific methods we've developed:
  - Ridge regression
  - Lasso regression
  - Support Vector Machines
- Our hypothesis space for these was all affine functions on  $R^d$ :

$$\mathcal{F} = \left\{ x \mapsto w^T x + b \mid w \in \mathbb{R}^d, b \in \mathbb{R} \right\}.$$

• What if we want to do prediction on inputs not natively in  $R^d$ ?

# The Input Space $\mathfrak X$

- Often want to use inputs not natively in R<sup>d</sup>:
  - Text documents
  - Image files
  - Sound recordings
  - DNA sequences
- But everything in a computer is a sequence of numbers
  - The ith entry of each sequence should have the same "meaning"
  - All the sequences should have the same length

#### Feature Extraction

#### Definition

Mapping an input from X to a vector in  $R^d$  is called **feature extraction** or **featurization**.

## Raw Input

### Feature Vector

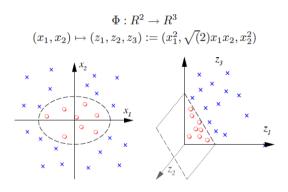

# Linear Models with Explicit Feature Map

- Input space: X (no assumptions)
- Introduce feature map  $\phi: \mathcal{X} \to \mathbb{R}^d$
- The feature map maps into the feature space  $R^d$ .
- Hypothesis space of affine functions on feature space:

$$\mathcal{F} = \left\{ x \mapsto w^T \varphi(x) + b \mid w \in \mathbb{R}^d, b \in \mathbb{R} \right\}.$$

# Geometric Example: Two class problem, nonlinear boundary

- With identity feature map  $\phi(x) = (x_1, x_2)$  and linear models, can't separate regions
- With appropriate featurization  $\phi(x) = (x_1, x_2, x_1^2 + x_2^2)$ , becomes linearly separable .
- Video: http://voutu.be/3liCbRZPrZA

## Expressivity of Hypothesis Space

- For linear models, to grow the hypothesis spaces, we must add features.
- Sometimes we say a larger hypothesis is more expressive.
  - (can fit more relationships between input and action)
- Many ways to create new features.

Handling Nonlinearity with Linear Methods

## Example Task: Predicting Health

- General Philosophy: Extract every feature that might be relevant
- Features for medical diagnosis
  - height
  - weight
  - body temperature
  - blood pressure
  - etc...

### Feature Issues for Linear Predictors

- For linear predictors, it's important how features are added
  - The relation between a feature and the label may not be linear
  - There may be complex dependence among features
- Three types of nonlinearities can cause problems:
  - Non-monotonicity
  - Saturation
  - Interactions between features

### Non-monotonicity: The Issue

- Feature Map:  $\phi(x) = [1, temperature(x)]$
- Action: Predict health score  $y \in R$  (positive is good)
- Hypothesis Space  $\mathcal{F}$ ={affine functions of temperature}
- Issue:
  - Health is not an affine function of temperature.
  - Affine function can either say
    - Very high is bad and very low is good, or
    - Very low is bad and very high is good,
    - But here, both extremes are bad.

### Non-monotonicity: Solution 1

• Transform the input:

$$\phi(x) = \left[1, \{\text{temperature}(x) - 37\}^2\right],$$

where 37 is "normal" temperature in Celsius.

- Ok, but requires manually-specified domain knowledge
  - Do we really need that?
  - What does  $w^T \phi(x)$  look like?

### Non-monotonicity: Solution 2

• Think less, put in more:

$$\phi(x) = \left[1, temperature(x), \{temperature(x)\}^2\right].$$

More expressive than Solution 1.

#### General Rule

Features should be simple building blocks that can be pieced together.

#### Saturation: The Issue

- Setting: Find products relevant to user's query
- Input: Product x
- Action: Score the relevance of x to user's query
- Feature Map:

$$\phi(x) = [1, N(x)],$$

- where N(x) = number of people who bought x.
- We expect a monotonic relationship between N(x) and relevance, but also expect diminishing return.

### Saturation: Solve with nonlinear transform

• Smooth nonlinear transformation:

$$\phi(x) = [1, \log\{1 + N(x)\}]$$

- ullet log  $(\cdot)$  good for values with large dynamic ranges
- Discretization (a discontinuous transformation):

$$\phi(x) = (1(0 \leqslant N(x) < 10), 1(10 \leqslant N(x) < 100), \ldots)$$

• Small buckets allow quite flexible relationship

#### Interactions: The Issue

- Input: Patient information x
- Action: Health score  $y \in R$  (higher is better)
- Feature Map

$$\phi(x) = [\mathsf{height}(x), \mathsf{weight}(x)]$$

- Issue: It's the weight *relative* to the height that's important.
- Impossible to get with these features and a linear classifier.
- Need some interaction between height and weight.

# Interactions: Approach 1

- Google "ideal weight from height"
- J. D. Robinson's "ideal weight" formula (for a male):

$$weight(kg) = 52 + 1.9 [height(in) - 60]$$

• Make score square deviation between height(h) and ideal weight(w)

$$f(x) = (52 + 1.9 [h(x) - 60] - w(x))^{2}$$

WolframAlpha for complicated Mathematics:

$$f(x) = 3.61h(x)^2 - 3.8h(x)w(x) - 235.6h(x) + w(x)^2 + 124w(x) + 3844$$

From Percy Liang's "Lecture 3" slides from Stanford's CS221, Autumn 2014.

# Interactions: Approach 2

• Just include all second order features:

$$\phi(x) = \left[1, h(x), w(x), h(x)^2, w(x)^2, \underbrace{h(x)w(x)}_{\text{cross term}}\right]$$

More flexible, no Google, no WolframAlpha.

### General Principle

Simpler building blocks replace a single "smart" feature.

#### Monomial Interaction Terms

Interaction terms are useful building blocks to model non-linearities in features.

- Suppose we start with  $x = (1, x_1, \dots, x_d) \in \mathbb{R}^{d+1} = \mathfrak{X}$ .
- Consider adding all **monomials** of degree M:  $x_1^{p_1} \cdots x_d^{p_d}$ , with  $p_1 + \cdots + p_d = M$ .
  - Monomials with degree 2 in 2D space:  $x_1^2$ ,  $x_2^2$ ,  $x_1x_2$
- How many features will we end up with?  $\binom{M+d-1}{M}$  ("stars and bars")
- This leads to extremely large data matrices
  - For d = 40 and M = 8, we get 314457495 features.

## Big Feature Spaces

Very large feature spaces have two potential issues:

- Overfitting
- Memory and computational costs

#### Solutions:

- Overfitting we handle with regularization.
- Kernel methods can help with memory and computational costs when we go to high (or infinite) dimensional spaces.

# The Kernel Trick

# SVM with Explicit Feature Map

- Let  $\psi: \mathfrak{X} \to \mathsf{R}^d$  be a feature map.
- The SVM objective (with explicit feature map):

$$\min_{w \in \mathbb{R}^d} \frac{1}{2} ||w||^2 + \frac{c}{n} \sum_{i=1}^n \max (0, 1 - y_i w^T \psi(x_i)).$$

- Computation is costly if d is large (e.g. with high-degree monomials)
- Last time we mentioned an equivalent optimization problem from Lagrangian duality.

#### SVM Dual Problem

• By Lagrangian duality, it is equivalent to solve the following dual problem:

maximize 
$$\sum_{i=1}^{n} \alpha_{i} - \frac{1}{2} \sum_{i,j=1}^{n} \alpha_{i} \alpha_{j} y_{i} y_{j} \psi(x_{j})^{T} \psi(x_{i})$$
s.t. 
$$\sum_{i=1}^{n} \alpha_{i} y_{i} = 0 \quad \text{and} \quad \alpha_{i} \in \left[0, \frac{c}{n}\right] \quad \forall i.$$

• If  $\alpha^*$  is an optimal value, then

$$w^* = \sum_{i=1}^n \alpha_i^* y_i \psi(x_i)$$
 and  $\hat{f}(x) = \sum_{i=1}^n \alpha_i^* y_i \psi(x_i)^T \psi(x)$ .

• Key observation:  $\psi(x)$  only shows up in inner products with another  $\psi(x')$  for both training and inference.

# Compute the Inner Products

Consider 2D data. Let's introduce degree-2 monomials using  $\psi: R^2 \to R^3$ .

$$(x_1, x_2) \mapsto (x_1^2, \sqrt{2}x_1x_2, x_2^2).$$

The inner product is

$$\psi(x)^{T}\psi(x') = x_{1}^{2}x_{1}'^{2} + (\sqrt{2}x_{1}x_{2})(\sqrt{2}x_{1}'x_{2}') + x_{2}^{2}x_{2}'^{2}$$

$$= (x_{1}x_{1}')^{2} + 2(x_{1}x_{1}')(x_{2}x_{2}') + (x_{2}x_{2}')^{2}$$

$$= (x_{1}x_{1}' + x_{2}x_{2}')^{2}$$

$$= (x^{T}x')^{2}$$

We can calculate the inner product  $\psi(x)^T \psi(x')$  in the original input space without accessing the features  $\psi(x)$ !

# Compute the Inner Products

Now, consider monomials up to degree-2:

$$(x_1, x_2) \mapsto (1, \sqrt{2}x_1, \sqrt{2}x_2, x_1^2, \sqrt{2}x_1x_2, x_2^2).$$

The inner product can be computed by

$$\psi(x)^T \psi(x') = (1 + x^T x')^2$$
 (check).

More generally, for features maps producing monomials up to degree-p, we have

$$\psi(x)^T \psi(x') = (1 + x^T x')^p.$$

(Note that the coefficients of each monomial in  $\psi$  may not be 1)

Kernel trick: we do not need explicit features to calculate inner products.

- Using explicit features:  $O(d^p)$
- Using implicit computation: O(d)

## Kernel Function

### The Kernel Function

- ullet Input space:  $\chi$
- Feature space:  $\mathcal{H}$  (a Hilbert space, e.g.  $R^d$ )
- Feature map:  $\psi: \mathfrak{X} \to \mathcal{H}$
- The kernel function corresponding to  $\psi$  is

$$k(x,x') = \langle \psi(x), \psi(x') \rangle$$
,

where  $\langle \cdot, \cdot \rangle$  is the inner product associated with  $\mathcal{H}$ .

Why introduce this new notation k(x,x')?

• We can often evaluate k(x,x') without explicitly computing  $\psi(x)$  and  $\psi(x')$ .

When can we use the kernel trick?

### Some Methods Can Be "Kernelized"

#### Definition

A method is **kernelized** if every feature vector  $\psi(x)$  only appears inside an inner product with another feature vector  $\psi(x')$ . This applies to both the optimization problem and the prediction function.

The SVM Dual is a kernelization of the original SVM formulation.

Optimization:

maximize 
$$\sum_{i=1}^{n} \alpha_{i} - \frac{1}{2} \sum_{i,j=1}^{n} \alpha_{i} \alpha_{j} y_{i} y_{j} \psi(x_{j})^{T} \psi(x_{i})$$

s.t. 
$$\sum_{i=1}^{n} \alpha_i y_i = 0$$
 and  $\alpha_i \in \left[0, \frac{c}{n}\right] \quad \forall i$ .

Prediction:

$$\hat{f}(x) = \sum_{i=1}^{n} \alpha_i^* y_i \psi(x_i)^T \psi(x).$$
DS-GA 1003

### The Kernel Matrix

#### Definition

The **kernel matrix** for a kernel k on  $x_1, \ldots, x_n \in \mathcal{X}$  is

$$K = (k(x_i, x_j))_{i,j} = \begin{pmatrix} k(x_1, x_1) & \cdots & k(x_1, x_n) \\ \vdots & \ddots & \cdots \\ k(x_n, x_1) & \cdots & k(x_n, x_n) \end{pmatrix} \in \mathbb{R}^{n \times n}.$$

• In ML this is also called a **Gram matrix**, but traditionally (in linear algebra), Gram matrices are defined without reference to a kernel or feature map.

### The Kernel Matrix

- The kernel matrix summarizes all the information we need about the training inputs  $x_1, \ldots, x_n$  to solve a kernelized optimization problem.
- In the kernelized SVM, we can replace  $\psi(x_i)^T \psi(x_j)$  with  $K_{ij}$ :

$$\begin{aligned} \text{maximize}_{\alpha} & & \sum_{i=1}^{n} \alpha_{i} - \frac{1}{2} \sum_{i,j=1}^{n} \alpha_{i} \alpha_{j} y_{i} y_{j} K_{ij} \\ \text{s.t.} & & \sum_{i=1}^{n} \alpha_{i} y_{i} = 0 \quad \text{and} \quad \alpha_{i} \in \left[0, \frac{c}{n}\right] \ i = 1, \dots, n. \end{aligned}$$

#### Kernel Methods

Given a kernelized ML algorithm (i.e. all  $\psi(x)$ 's show up as  $\langle \psi(x), \psi(x') \rangle$ ),

- Can swap out the inner product for a new kernel function.
- New kernel may correspond to a very high-dimensional feature space.
- Once the kernel matrix is computed, the computational cost depends on number of data points *n*, rather than the dimension of feature space *d*.
- Useful when d >> n.
- Computing the kernel matrix may still depend on d and the essence of the **trick** is getting around this O(d) dependence.

Example Kernels

# Kernels as Similarity Scores

- Often useful to think of the k(x,x') as a similarity score for x and x'.
- We can design similarity functions without thinking about the explicit feature map, e.g. "string kernels", "graph kerners".
- How do we know that our kernel functions actually correspond to inner products in some feature space?

### How to Get Kernels?

- Explicitly construct  $\psi(x): \mathcal{X} \to \mathsf{R}^d$  (e.g. monomials) and define  $k(x,x') = \psi(x)^T \psi(x')$ .
- Directly define the kernel function k(x,x') ("similarity score"), and verify it corresponds to  $\langle \psi(x), \psi(x') \rangle$  for some  $\psi$ .

There are many theorems to help us with the second approach.

Linear Algebra Review: Positive Semidefinite Matrices

#### Definition

A real, symmetric matrix  $M \in \mathbb{R}^{n \times n}$  is **positive semidefinite (psd)** if for any  $x \in \mathbb{R}^n$ ,

$$x^T M x \geqslant 0.$$

#### Theorem

The following conditions are each necessary and sufficient for a symmetric matrix M to be positive semidefinite:

- M can be factorized as  $M = R^T R$ , for some matrix R.
- All eigenvalues of M are greater than or equal to 0.

### Positive Definite Kernel

#### Definition

A symmetric function  $k: \mathcal{X} \times \mathcal{X} \to \mathsf{R}$  is a **positive definite (pd)** kernel on  $\mathcal{X}$  if for any finite set  $\{x_1, \ldots, x_n\} \in \mathcal{X}$   $(n \in \mathbb{N})$ , the kernel matrix on this set

$$K = (k(x_i, x_j))_{i,j} = \begin{pmatrix} k(x_1, x_1) & \cdots & k(x_1, x_n) \\ \vdots & \ddots & \cdots \\ k(x_n, x_1) & \cdots & k(x_n, x_n) \end{pmatrix}$$

is a positive semidefinite matrix.

- Symmetric: k(x,x') = k(x',x)
- The kernel matrix needs to be positive semidefinite for any finite set of points.
- Equivalent definition:  $\sum_{i=1}^{n} \sum_{j=1}^{n} \alpha_i \alpha_j k(x_i, x_j) \ge 0$  given  $\alpha_i \in \mathbb{R} \ \forall i$ .

### Mercer's Theorem

#### Theorem

A symmetric function k(x,x') can be expressed as an inner product

$$k(x,x') = \langle \psi(x), \psi(x') \rangle$$

for some  $\psi$  if and only if k(x,x') is **positive definite**.

- Proving a kernel function is positive definite is typically not easy.
- But we can construct new kernels from valid kernels.

## Generating New Kernels from Old

• Suppose k,  $k_1$ ,  $k_2$ :  $\mathfrak{X} \times \mathfrak{X} \to \mathsf{R}$  are pd kernels. Then so are the following:

$$\begin{array}{lll} k_{\mathsf{new}}(x,x') &=& \alpha k(x,x') \quad \text{for } \alpha \geqslant 0 \quad \text{(non-negative scaling)} \\ k_{\mathsf{new}}(x,x') &=& k_1(x,x') + k_2(x,x') \quad \text{(sum)} \\ k_{\mathsf{new}}(x,x') &=& k_1(x,x')k_2(x,x') \quad \text{(product)} \\ k_{\mathsf{new}}(x,x') &=& k(\psi(x),\psi(x')) \quad \text{for any function } \psi(\cdot) \quad \text{(recursion)} \\ k_{\mathsf{new}}(x,x') &=& f(x)f(x') \quad \text{for any function } f(\cdot) \quad \text{($f$ as 1D feature map)} \end{array}$$

• Lots more theorems to help you construct new kernels from old.

Based on Mark Schmidt's slides:https://www.cs.ubc.ca/~schmidtm/Courses/540-W19/L12.5.pdf

### Linear Kernel

- Input space:  $\mathfrak{X} = \mathbb{R}^d$
- Feature space:  $\mathcal{H} = \mathbb{R}^d$ , with standard inner product
- Feature map

$$\psi(x) = x$$

• Kernel:

$$k(x,x') = x^T x'$$

# Quadratic Kernel in R<sup>d</sup>

- Input space  $\mathfrak{X} = \mathsf{R}^d$
- Feature space:  $\mathcal{H} = \mathbb{R}^D$ , where  $D = d + \binom{d}{2} \approx d^2/2$ .
- Feature map:

$$\psi(x) = (x_1, \dots, x_d, x_1^2, \dots, x_d^2, \sqrt{2}x_1x_2, \dots, \sqrt{2}x_ix_j, \dots \sqrt{2}x_{d-1}x_d)^T$$

• Then for  $\forall x, x' \in \mathbb{R}^d$ 

$$k(x,x') = \langle \psi(x), \psi(x') \rangle$$
  
=  $\langle x, x' \rangle + \langle x, x' \rangle^2$ 

- Computation for inner product with explicit mapping:  $O(d^2)$
- Computation for implicit kernel calculation: O(d).

# Polynomial Kernel in R<sup>d</sup>

- Input space  $\mathfrak{X} = \mathbb{R}^d$
- Kernel function:

$$k(x,x') = (1 + \langle x,x' \rangle)^M$$

- $\bullet$  Corresponds to a feature map with all monomials up to degree M.
- For any M, computing the kernel has same computational cost
- Cost of explicit inner product computation grows rapidly in *M*.

# Radial Basis Function (RBF) / Gaussian Kernel

Input space  $\mathfrak{X} = \mathbb{R}^d$ 

$$k(x,x') = \exp\left(-\frac{\|x-x'\|^2}{2\sigma^2}\right),\,$$

where  $\sigma^2$  is known as the bandwidth parameter.

- Probably the most common nonlinear kernel.
- Does it act like a similarity score?
- Have we departed from our "inner product of feature vector" recipe?
  - Yes and no: corresponds to an infinite dimensional feature vector

### Remaining Questions

#### Our current recipe:

- Recognize kernelized problem:  $\psi(x)$  only occur in inner products  $\psi(x)^T \psi(x')$
- Pick a kernel function ("similarity score")
- Compute the kernel matrix (n by n where n is the dataset size)
- Optimize the model and make predictions by accessing the kernel matrix

Next: When can we apply kernelization?

Representer Theorem

## SVM solution is in the "span of the data"

We found the SVM dual problem can be written as:

$$\sup_{\alpha \in \mathbb{R}^n} \qquad \sum_{i=1}^n \alpha_i - \frac{1}{2} \sum_{i,j=1}^n \alpha_i \alpha_j y_i y_j x_j^T x_i$$
s.t. 
$$\sum_{i=1}^n \alpha_i y_i = 0$$

$$\alpha_i \in \left[0, \frac{c}{n}\right] \ i = 1, \dots, n.$$

- Given dual solution  $\alpha^*$ , primal solution is  $w^* = \sum_{i=1}^n \alpha_i^* y_i x_i$ .
- Notice:  $w^*$  is a linear combination of training inputs  $x_1, \ldots, x_n$ .
- We refer to this phenomenon by saying " $w^*$  is in the span of the data."
  - Or in math,  $w^* \in \text{span}(x_1, \dots, x_n)$ .

## Ridge regression solution is in the "span of the data"

• The ridge regression solution for regularization parameter  $\lambda > 0$  is

$$w^* = \arg\min_{w \in \mathbb{R}^d} \frac{1}{n} \sum_{i=1}^n \left\{ w^T x_i - y_i \right\}^2 + \lambda ||w||_2^2.$$

• This has a closed form solution (Homework #3):

$$w^* = \left(X^T X + \lambda I\right)^{-1} X^T y,$$

where X is the design matrix, with  $x_1, \ldots, x_n$  as rows.

Ridge regression solution is in the "span of the data"

• Rearranging  $w^* = (X^T X + \lambda I)^{-1} X^T y$ , we can show that (also Homework #3):

$$w^* = X^T \underbrace{\left(\frac{1}{\lambda}y - \frac{1}{\lambda}Xw^*\right)}_{\alpha^*}$$
$$= X^T \alpha^* = \sum_{i=1}^n \alpha_i^* x_i.$$

- So  $w^*$  is in the span of the data.
  - i.e.  $w^* \in \operatorname{span}(x_1, \ldots, x_n)$

## If solution is in the span of the data, we can reparameterize

• The ridge regression solution for regularization parameter  $\lambda > 0$  is

$$w^* = \arg\min_{w \in \mathbb{R}^d} \frac{1}{n} \sum_{i=1}^n \left\{ w^T x_i - y_i \right\}^2 + \lambda ||w||_2^2.$$

- We now know that  $w^* \in \operatorname{span}(x_1, \ldots, x_n) \subset \mathbb{R}^d$ .
- So rather than minimizing over all of  $\mathbb{R}^d$ , we can minimize over span  $(x_1, \dots, x_n)$ .

$$w^* = \underset{w \in \text{span}(x_1, ..., x_n)}{\arg \min} \frac{1}{n} \sum_{i=1}^n \{ w^T x_i - y_i \}^2 + \lambda ||w||_2^2.$$

ullet Let's reparameterize the objective by replacing w as a linear combination of the inputs.

If solution is in the span of the data, we can reparameterize

- Note that for any  $w \in \text{span}(x_1, \dots, x_n)$ , we have  $w = X^T \alpha$ , for some  $\alpha \in \mathbb{R}^n$ .
- So let's replace w with  $X^T \alpha$  in our optimization problem:

- To get  $w^*$  from the reparameterized optimization problem, we just take  $w^* = X^T \alpha^*$ .
- We changed the dimension of our optimization variable from d to n. Is this useful?

## Consider very large feature spaces

- Suppose we have a 300-million dimension feature space [very large]
  - (e.g. using high order monomial interaction terms as features, as described last lecture)
- Suppose we have a training set of 300,000 examples [fairly large]
- In the original formulation, we solve a 300-million dimension optimization problem.
- In the reparameterized formulation, we solve a 300,000-dimension optimization problem.
- This is why we care about when the solution is in the span of the data.
- This reparameterization is interesting when we have more features than data  $(d \gg n)$ .

### What's next?

- For SVM and ridge regression, we found that the solution is in the span of the data.
  - derived in two rather ad-hoc ways
- Up next: The Representer Theorem, which shows that this "span of the data" result occurs far more generally, and we prove it using basic linear algebra.

Math Review: Inner Product Spaces and Hilbert Spaces

## Hypothesis spaces we've seen so far

Finite-dimensional vector space (linear functions):

$$\mathcal{H} = \{ f : \mathcal{X} \to \mathsf{R} \mid f(x) = w^T x, \quad w, x \in \mathsf{R}^d \} .$$

To consider more complex input spaces (e.g. text, images), we use a feature map  $\phi: \mathcal{X} \to \mathcal{F}$ :

$$\mathcal{H} = \{ f \colon \mathcal{X} \to \mathsf{R} \mid f(x) = w^T \varphi(x) \} .$$

- Φ does not have to be linear.
- ullet The feature space  ${\mathcal F}$  can be  ${\mathsf R}^d$  (Euclidean space) or an infinite-dimensional vector space.
- We would like more structure on  $\mathcal{F}$ .

## Inner Product Space (or "Pre-Hilbert" Spaces)

An inner product space (over reals) is a vector space  $\mathcal V$  with an inner product, which is a mapping

$$\langle \cdot, \cdot \rangle : \mathcal{V} \times \mathcal{V} \to \mathsf{R}$$

that has the following properties:  $\forall x, y, z \in \mathcal{V}$  and  $a, b \in \mathbb{R}$ :

- Symmetry:  $\langle x, y \rangle = \langle y, x \rangle$
- Linearity:  $\langle ax + by, z \rangle = a \langle x, z \rangle + b \langle y, z \rangle$
- Positive-definiteness:  $\langle x, x \rangle \geqslant 0$  and  $\langle x, x \rangle = 0 \iff x = 0_{\mathcal{V}}$ .

To show a function  $\langle \cdot, \cdot \rangle$  is an inner product, we need to check the above conditions.

Exercise: show that  $\langle x, y \rangle \stackrel{\text{def}}{=} x^T y$  is an inner product on  $\mathbb{R}^d$ .

### Norm from Inner Product

Inner product is nice because it gives us notions of "size", "distance", "angle" in the vector space.

For an inner product space, we can ddefine a norm as

$$||x|| \stackrel{\text{def}}{=} \sqrt{\langle x, x \rangle}.$$

Example

 $R^d$  with standard Euclidean inner product is an inner product space:

$$\langle x, y \rangle := x^T y \qquad \forall x, y \in \mathbb{R}^d.$$

Norm is

$$||x|| = \sqrt{x^T x}$$
.

# Orthogonality (Definitions)

#### Definition

Two vectors are **orthogonal** if  $\langle x, x' \rangle = 0$ . We denote this by  $x \perp x'$ .

#### Definition

x is orthogonal to a set S, i.e.  $x \perp S$ , if  $x \perp s$  for all  $x \in S$ .

# Pythagorean Theorem

### Theorem (Pythagorean Theorem)

If 
$$x \perp x'$$
, then  $||x + x'||^2 = ||x||^2 + ||x'||^2$ .

### Proof.

We have

$$\begin{aligned} \|x + x'\|^2 &= \langle x + x', x + x' \rangle \\ &= \langle x, x \rangle + \langle x, x' \rangle + \langle x', x \rangle + \langle x', x' \rangle \\ &= \|x\|^2 + \|x'\|^2. \end{aligned}$$

### Hilbert Space

- A pre-Hilbert space is a vector space equipped with an inner product.
- We need an additional technical condition for Hilbert space: completeness.
- A space is **complete** if all Cauchy sequences in the space converge to a point in the space.

#### Definition

A Hilbert space is a complete inner product space.

#### Example

Any finite dimensional inner produce space is a Hilbert space.

The Representer Theorem

## Generalize from SVM Objective

• SVM objective:

$$\min_{w \in \mathbb{R}^d} \frac{1}{2} ||w||^2 + \frac{c}{n} \sum_{i=1}^n \max(0, 1 - y_i [\langle w, x_i \rangle]).$$

• Generalized objective:

$$\min_{w \in \mathcal{H}} R(\|w\|) + L(\langle w, x_1 \rangle, \dots, \langle w, x_n \rangle),$$

where

- $w, x_1, \dots, x_n \in \mathcal{H}$  for some Hilbert space  $\mathcal{H}$ . (We typically have  $\mathcal{H} = \mathbb{R}^d$ .)
- $\|\cdot\|$  is the norm corresponding to the inner product of  $\mathcal{H}$ . (i.e.  $\|w\| = \sqrt{\langle w, w \rangle}$ )
- $R:[0,\infty)\to R$  is nondecreasing (Regularization term), and
- $L: \mathbb{R}^n \to \mathbb{R}$  is arbitrary (Loss term).

# General Objective Function for Linear Hypothesis Space (Details)

Generalized objective:

$$\min_{w \in \mathcal{H}} R(\|w\|) + L(\langle w, x_1 \rangle, \dots, \langle w, x_n \rangle)$$

- We can map  $x_i$  to a feature space.
- The prediction/score function  $x \mapsto \langle w, x \rangle$  is linear in w.

# General Objective Function for Linear Hypothesis Space (Details)

Generalized objective:

$$\min_{w \in \mathcal{H}} R(\|w\|) + L(\langle w, x_1 \rangle, \dots, \langle w, x_n \rangle)$$

- Ridge regression and SVM are of this form. (Verify this!)
- What if we penalize with  $\lambda ||w||_2$  instead of  $\lambda ||w||_2^2$ ? Yes!
- ullet What if we use lasso regression? No!  $\ell_1$  norm does not correspond to an inner product.

## The Representer Theorem: Quick Summary

• Generalized objective:

$$w^* = \arg\min_{w \in \mathcal{H}} R(\|w\|) + L(\langle w, x_1 \rangle, \dots, \langle w, x_n \rangle)$$

• Representer theorem tells us we can look for  $w^*$  in the span of the data:

$$w^* = \underset{w \in \operatorname{span}(x_1, \dots, x_n)}{\operatorname{arg\,min}} R(\|w\|) + L(\langle w, x_1 \rangle, \dots, \langle w, x_n \rangle).$$

• So we can reparameterize as before:

$$\alpha^* = \arg\min_{\alpha \in \mathbb{R}^n} R\left( \left\| \sum_{i=1}^n \alpha_i x_i \right\| \right) + L\left( \left\langle \sum_{i=1}^n \alpha_i x_i, x_1 \right\rangle, \dots, \left\langle \sum_{i=1}^n \alpha_i x_i, x_n \right\rangle \right).$$

• Our reparameterization trick applies much more broadly than SVM and ridge.

### The Representer Theorem

### Theorem (Representer Theorem)

Let

$$J(w) = R(||w||) + L(\langle w, x_1 \rangle, \dots, \langle w, x_n \rangle),$$

where

- $w, x_1, ..., x_n \in \mathcal{H}$  for some Hilbert space  $\mathcal{H}$ . (We typically have  $\mathcal{H} = R^d$ .)
- $\|\cdot\|$  is the norm corresponding to the inner product of  $\mathfrak{H}$ . (i.e.  $\|w\| = \sqrt{\langle w, w \rangle}$ )
- $R:[0,\infty)\to R$  is nondecreasing (Regularization term), and
- $L: \mathbb{R}^n \to \mathbb{R}$  is arbitrary (Loss term).

Then it has a minimizer of the form  $w^* = \sum_{i=1}^n \alpha_i x_i$ .

The Representer Theorem (Proof sketch)

Reparameterizing our Generalized Objective Function

### Rewriting the Objective Function

• Define the training score function  $s: \mathbb{R}^d \to \mathbb{R}^n$  by

$$s(w) = \begin{pmatrix} \langle w, x_1 \rangle \\ \vdots \\ \langle w, x_n \rangle \end{pmatrix},$$

which gives the training score vector for any w.

• We can then rewrite the objective function as

$$J(w) = R(||w||) + L(s(w)),$$

where now  $L: \mathbb{R}^{n \times 1} \to \mathbb{R}$  takes a column vector as input.

• This will allow us to have a slick reparameterized version...

## Reparameterize the Generalized Objective

- By the Representer Theorem, it's sufficient to minimize J(w) for w of the form  $\sum_{i=1}^{n} \alpha_i x_i$ .
- Plugging this form into J(w), we see we can just minimize

$$J_0(\alpha) = R\left(\left\|\sum_{i=1}^n \alpha_i x_i\right\|\right) + L\left(s\left(\sum_{i=1}^n \alpha_i x_i\right)\right)$$

over 
$$\alpha = (\alpha_1, \dots, \alpha_n)^T \in \mathbb{R}^{n \times 1}$$
.

- With some new notation, we can substantially simplify
  - the norm piece  $||w|| = ||\sum_{i=1}^{n} \alpha_i x_i||$ , and
  - the score piece  $s(w) = s(\sum_{i=1}^{n} \alpha_i x_i)$ .

## Simplifying the Reparameterized Norm

• For the norm piece  $||w|| = ||\sum_{i=1}^{n} \alpha_i x_i||$ , we have

$$||w||^{2} = \langle w, w \rangle$$

$$= \left\langle \sum_{i=1}^{n} \alpha_{i} x_{i}, \sum_{j=1}^{n} \alpha_{j} x_{j} \right\rangle$$

$$= \sum_{i,j=1}^{n} \alpha_{i} \alpha_{j} \langle x_{i}, x_{j} \rangle.$$

- This expression involves the  $n^2$  inner products between all pairs of input vectors.
- We often put those values together into a matrix (Gram/Kernel matrix).

### Example: Gram Matrix for the Dot Product

- Consider  $x_1, \ldots, x_n \in \mathbb{R}^{d \times 1}$  with the standard inner product  $\langle x, x' \rangle = x^T x'$ .
- Let  $X \in \mathbb{R}^{n \times d}$  be the **design matrix**, which has each input vector as a row:

$$X = \begin{pmatrix} -x_1^T - \\ \vdots \\ -x_n^T - \end{pmatrix}.$$

• Then the Gram matrix is

$$K = \begin{pmatrix} x_1^T x_1 & \cdots & x_1^T x_n \\ \vdots & \ddots & \cdots \\ x_n^T x_1 & \cdots & x_n^T x_n \end{pmatrix} = \begin{pmatrix} -x_1^T - \\ \vdots \\ -x_n^T - \end{pmatrix} \begin{pmatrix} | & \cdots & | \\ x_1 & \cdots & x_n \\ | & \cdots & | \end{pmatrix}$$
$$= \mathbf{X} \mathbf{X}^T$$

# Simplifying the Reparametrized Norm

• With  $w = \sum_{i=1}^{n} \alpha_i x_i$ , we have

$$||w||^{2} = \langle w, w \rangle$$

$$= \left\langle \sum_{i=1}^{n} \alpha_{i} x_{i}, \sum_{j=1}^{n} \alpha_{j} x_{j} \right\rangle$$

$$= \sum_{i,j=1}^{n} \alpha_{i} \alpha_{j} \langle x_{i}, x_{j} \rangle$$

$$= \alpha^{T} K \alpha.$$

## Simplifying the Training Score Vector

• The score for  $x_j$  for  $w = \sum_{i=1}^n \alpha_i x_i$  is

$$\langle w, x_j \rangle = \left\langle \sum_{i=1}^n \alpha_i x_i, x_j \right\rangle = \sum_{i=1}^n \alpha_i \left\langle x_i, x_j \right\rangle$$

• The training score vector is

$$s\left(\sum_{i=1}^{n}\alpha_{i}x_{i}\right) = \begin{pmatrix} \sum_{i=1}^{n}\alpha_{i}\langle x_{i}, x_{1}\rangle \\ \vdots \\ \sum_{i=1}^{n}\alpha_{i}\langle x_{i}, x_{n}\rangle \end{pmatrix} = \begin{pmatrix} \alpha_{1}\langle x_{1}, x_{1}\rangle + \dots + \alpha_{n}\langle x_{n}, x_{1}\rangle \\ \vdots \\ \alpha_{1}\langle x_{1}, x_{n}\rangle + \dots + \alpha_{n}\langle x_{n}, x_{n}\rangle \end{pmatrix}$$
$$= \begin{pmatrix} \langle x_{1}, x_{1}\rangle & \dots & \langle x_{1}, x_{n}\rangle \\ \vdots & \ddots & \dots \\ \langle x_{n}, x_{1}\rangle & \dots & \langle x_{n}, x_{n}\rangle \end{pmatrix} \begin{pmatrix} \alpha_{1} \\ \vdots \\ \alpha_{n} \end{pmatrix}$$
$$= K\alpha$$

### Reparameterized Objective

Putting it all together, our reparameterized objective function can be written as

$$J_0(\alpha) = R\left(\left\|\sum_{i=1}^n \alpha_i x_i\right\|\right) + L\left(s\left(\sum_{i=1}^n \alpha_i x_i\right)\right)$$
$$= R\left(\sqrt{\alpha^T K \alpha}\right) + L(K\alpha),$$

which we minimize over  $\alpha \in \mathbb{R}^n$ .

- All information needed about  $x_1, \ldots, x_n$  is summarized in the Gram matrix K.
- We're now minimizing over  $R^n$  rather than  $R^d$ .
- If  $d \gg n$ , this can be a big win computationally (at least once K is computed).

## Reparameterizing Predictions

Suppose we've found

$$\alpha^* \in \operatorname*{arg\,min}_{\alpha \in \mathsf{R}^n} R\left(\sqrt{\alpha^T K \alpha}\right) + L\left(K\alpha\right).$$

• Then we know  $w^* = \sum_{i=1}^n \alpha^* x_i$  is a solution to

$$\underset{w \in \mathcal{H}}{\operatorname{arg\,min}} R(\|w\|) + L(\langle w, x_1 \rangle, \dots, \langle w, x_n \rangle).$$

• The prediction on a new point  $x \in \mathcal{H}$  is

$$\hat{f}(x) = \langle w^*, x \rangle = \sum_{i=1}^n \alpha_i^* \langle x_i, x \rangle.$$

• To make a new prediction, we may need to touch all the training inputs  $x_1, \ldots, x_n$ .

### More Notation

• It will be convenient to define the following column vector for any  $x \in \mathcal{H}$ :

$$k_{\mathsf{x}} = \begin{pmatrix} \langle \mathsf{x}_1, \mathsf{x} \rangle \\ \vdots \\ \langle \mathsf{x}_n, \mathsf{x} \rangle \end{pmatrix}$$

• Then we can write our predictions on a new point x as

$$\hat{f}(x) = k_x^T \alpha^*$$

## Summary So Far

- Original plan:
  - Find  $w^* \in \operatorname{arg\,min}_{w \in \mathcal{H}} R(\|w\|) + L(\langle w, x_1 \rangle, \dots, \langle w, x_n \rangle)$
  - Predict with  $\hat{f}(x) = \langle w^*, x \rangle$ .
- We showed that the following is equivalent:
  - Find  $\alpha^* \in \operatorname{arg\,min}_{\alpha \in \mathbb{R}^n} R\left(\sqrt{\alpha^T K \alpha}\right) + L(K \alpha)$
  - Predict with  $\hat{f}(x) = k_x^T \alpha^*$ , where

$$K = \begin{pmatrix} \langle x_1, x_1 \rangle & \cdots & \langle x_1, x_n \rangle \\ \vdots & \ddots & \cdots \\ \langle x_n, x_1 \rangle & \cdots & \langle x_n, x_n \rangle \end{pmatrix} \quad \text{and} \quad k_x = \begin{pmatrix} \langle x_1, x \rangle \\ \vdots \\ \langle x_n, x \rangle \end{pmatrix}$$

• Every element  $x \in \mathcal{H}$  occurs inside an inner products with a training input  $x_i \in \mathcal{H}$ .

### Kernelization

#### **Definition**

A method is **kernelized** if every feature vector  $\psi(x)$  only appears inside an inner product with another feature vector  $\psi(x')$ . This applies to both the optimization problem and the prediction function.

• Here we are using  $\psi(x) = x$ . Thus finding

$$\alpha^* \in \operatorname*{arg\,min}_{\alpha \in \mathsf{R}^n} R\left(\sqrt{\alpha^T K \alpha}\right) + L(K \alpha)$$

and making predictions with  $\hat{f}(x) = k_x^T \alpha^*$  is a kernelization of finding

$$w^* \in \arg\min_{w \in \mathcal{H}} R(\|w\|) + L(\langle w, x_1 \rangle, \dots, \langle w, x_n \rangle)$$

and making predictions with  $\hat{f}(x) = \langle w^*, x \rangle$ .

### Summary

- We used duality for SVM and bare hands for ridge regression to find their kernelized version.
- Many other algorithms can be kernelized.
- Our principled tool for kernelization is reparameterization by the representer theorem.
- Representer theorem says that all norm-regularized linear models can be kernelized.
- ullet Once kernelized, we can apply the kernel trick: doesn't need to represent  $\varphi(x)$  explicitly.
